

MEC-E1050

**FINITE ELEMENT METHOD IN
SOLIDS 2024**

WHY FINITE ELEMENTS AND ITS THEORY?

Design of machines and structures: Solution to stress or displacement by analytical method is often impossible due to complex geometry, heterogeneous material etc. Lack of the “exact solution” to an “approximate problem” is not an issue in engineering work.

Finite element method is the standard of solid mechanics: Commercial codes in common use are based on the finite element method. A graphical user interface may make living easier, but a user should always understand what the problem is and in what sense it is solved!

Finite element method has a strong theory: Although approximate solution is acceptable, knowing nothing about the error is not acceptable.

Week 43-2

SOLID MECHANICS APPLICATION

Week 43-3

1 INTRODUCTION

1.1 STRUCTURE MODELLING.....	6
1.2 ENGINEERING MODELS	11
1.3 DISPLACEMENT ANALYSIS	25
1.4 FE-CODE OF MEC-E1050.....	31

LEARNING OUTCOMES

Students get an overall picture about prerequisites of the course, the roles of engineering models in structure modelling, and finite element method in displacement analysis of structures. The topics of the week are

- Structure modelling
- Engineering models
- Mathematica language and the finite element solver of MEC-E1050
- Prerequisites of MEC-E1050

1.1 STRUCTURE MODELLING

- **Crop:** Decide the boundary of a structure. Interaction with surroundings need to be described in terms of known forces, moments, displacements, and rotations. All uncertainties with this respect bring uncertainty to the model too.
- **Idealize:** Simplify the geometry. Ignoring the details not likely to affect the outcome may simplify the analysis a lot.
- **Parametrize:** Assign symbols to geometric and material parameters of the idealized structure. Measure or find the values needed in numerical calculations.
- **Divide-and-rule:** Consider a complex structure as a set of structural parts interacting through connection points and find solutions one-by-one. Combine the solutions using the force and displacement conditions at the connection points.

MODEL OF A THREE FLOOR BUILDING

Week 43-7

STRUCTURE IDEALIZATION AND ...

... PARAMETRIZATION

Parameter	symbol	value
Effective column diameter	d	0.0048 m
Room height	h	0.156 m
Column spacing (x)	l_x	0.4 m
Column spacing (y)	l_y	0.243 m
Floor length	L	0.44 m
Floor width	W	0.295 m
Floor thickness	t	0.015 m

FINITE ELEMENT SIMULATION

Week 43-10

1.2 ENGINEERING MODELS

- **Solid model:** A linearly elastic body represents the “precise model” of the course. The generic solid model is used when more efficient engineering models do not apply.
- **Plate model:** Structural part of one small dimension (thin body). Deformation is described by thin slab and plate bending modes. In curved geometry, the model is called as the shell model.
- **Beam model:** Structural part of two small dimensions (slender body). Deformation is described by a bar mode, two bending modes, and a torsion mode.
- **Rigid body:** Structural part of negligible deformation. The idealization is useful when rigidities of structural parts differ significantly.

SOLID MODEL

The primary unknowns are $u(x, y, z)$, $v(x, y, z)$, $w(x, y, z)$, $(\phi(x, y, z), \theta(x, y, z), \psi(x, y, z))$. Material elements may translate, rotate, and deform. In short, for points P and Q of an element $\vec{u}_Q = \vec{u}_P + \vec{\theta}_P \times \vec{\rho}_{PQ} + \vec{\rho}_{PQ} \cdot \vec{\epsilon}_P$. Displacement follows from stress-strain relationship (generalized Hooke's law) and equilibrium of material elements.

- Let us consider the displacement of a small material element centered at point P. As the material element is assumed to be small, first two terms of the Taylor series represent the displacement inside the material element

$$\vec{u}_Q = \vec{u}_P + \vec{\rho}_{PQ} \cdot (\nabla \vec{u})_P,$$

where the relative position vector $\vec{\rho}_{PQ} = \vec{r}_Q - \vec{r}_P$. Division of the displacement gradient into its anti-symmetric and symmetric parts $(\nabla \vec{u})_P = \vec{\theta}_P + \vec{\epsilon}_P$ and using the concept of an associated vector $\vec{\theta}$ to an antisymmetric tensor $\vec{\theta}$, gives

$$\vec{u}_Q = \vec{u}_P + \vec{\theta}_P \times \vec{\rho}_{PQ} + \vec{\rho}_{PQ} \cdot \vec{\epsilon}_P.$$

The terms describe effects of translation, small rigid body rotation, and deformation (shape distortion) when the rotation part is small. Stress acting on the material element depends only on strain $\vec{\epsilon}_P$.

EXAMPLE The cross section of a cylindrical body is square of side length h . Density ρ , Young's modulus E , and Poisson's ratio ν of the linearly elastic isotropic and homogeneous material are constants. The body is loaded by a constant traction of magnitude P/h^2 at its free end. Determine stress $\vec{\sigma}$ and displacement \vec{u} using the solid model. Assume that the transverse (to the axis) displacement is not constrained by the support.

Answer $u = -\frac{P}{Eh^2}x, \quad v = \nu \frac{P}{Eh^2}y, \quad w = \nu \frac{P}{Eh^2}z$

$$\sigma_{xx} = -\frac{P}{h^2}, \quad \sigma_{yy} = \sigma_{zz} = \sigma_{xy} = \sigma_{yz} = \sigma_{zx} = 0$$

- The component forms of the equilibrium equations and constitutive equations of a linearly elastic isotropic material in a Cartesian (x, y, z) –coordinate system are

$$\begin{Bmatrix} \partial \sigma_{xx} / \partial x + \partial \sigma_{yx} / \partial y + \partial \sigma_{zx} / \partial z + f_x \\ \partial \sigma_{xy} / \partial x + \partial \sigma_{yy} / \partial y + \partial \sigma_{zy} / \partial z + f_y \\ \partial \sigma_{xz} / \partial x + \partial \sigma_{yz} / \partial y + \partial \sigma_{zz} / \partial z + f_z \end{Bmatrix} = 0,$$

$$\begin{Bmatrix} \partial u / \partial x \\ \partial v / \partial y \\ \partial w / \partial z \end{Bmatrix} = \frac{1}{E} \begin{bmatrix} 1 & -\nu & -\nu \\ -\nu & 1 & -\nu \\ -\nu & -\nu & 1 \end{bmatrix} \begin{Bmatrix} \sigma_{xx} \\ \sigma_{yy} \\ \sigma_{zz} \end{Bmatrix}, \text{ and } \begin{Bmatrix} \sigma_{xy} \\ \sigma_{yz} \\ \sigma_{zx} \end{Bmatrix} = \begin{Bmatrix} \sigma_{yx} \\ \sigma_{zy} \\ \sigma_{xz} \end{Bmatrix} = G \begin{Bmatrix} \partial u / \partial y + \partial v / \partial x \\ \partial v / \partial z + \partial w / \partial y \\ \partial w / \partial x + \partial u / \partial z \end{Bmatrix}.$$

- Let us assume that the non-zero stress and displacement components are $\sigma_{xx}(x)$, $u(x)$, $v(y)$ and $w(z)$. The axial stress follows from the equilibrium equation and the known traction at the free end $x = L$:

$$\frac{d\sigma_{xx}}{dx} = 0 \quad 0 < x < L \quad \text{and} \quad \sigma_{xx}(L) = -\frac{P}{h^2} \quad \Rightarrow \quad \sigma_{xx}(x) = -\frac{P}{h^2}.$$

- Generalized Hooke's law written for the uniaxial stress implies that

$$\frac{du}{dx} = \frac{\sigma_{xx}}{E} = -\frac{P}{Eh^2}, \quad \frac{dv}{dy} = -\frac{\nu}{E}\sigma_{xx} = \nu\frac{P}{Eh^2}, \quad \frac{dw}{dz} = -\frac{\nu}{E}\sigma_{xx} = \nu\frac{P}{Eh^2}.$$

Axial displacement vanishes at the support and the transverse displacement at the axis:

$$\frac{du}{dx} = -\frac{P}{Eh^2} \quad 0 < x < L \quad \text{and} \quad u(0) = 0 \quad \Rightarrow \quad u(x) = -\frac{P}{Eh^2}x, \quad \leftarrow$$

$$\frac{dv}{dy} = \nu\frac{P}{Eh^2} \quad -\frac{1}{2}h < y < \frac{1}{2}h \quad \text{and} \quad v(0) = 0 \quad \Rightarrow \quad v(y) = \nu\frac{P}{Eh^2}y, \quad \leftarrow$$

$$\frac{dw}{dz} = -\nu\frac{P}{Eh^2} \quad -\frac{1}{2}h < z < \frac{1}{2}h \quad \text{and} \quad w(0) = 0 \quad \Rightarrow \quad w(z) = -\nu\frac{P}{Eh^2}z. \quad \leftarrow$$

EXAMPLE Consider a torsion of a cylindrical body of length L and circular cross-section of radius R . Shear modulus G of the material is constant. If one end is fixed and the other end is free to rotate, determine the relationship between torque T and rotation angle ψ at the free end. Assume that $u = -\psi(z)y$, $v = \psi(z)x$, and $w = 0$.

Answer $T = \frac{I_{rr}G}{L}\psi$ where $I_{rr} = \frac{\pi}{2}R^4$.

PLATE MODEL

Reissner-Mindlin

Kirchhoff

The primary unknowns are $u(x, y)$, $v(x, y)$, $w(x, y)$, $\phi(x, y)$, $\theta(x, y)$, $\psi(x, y)$. Line segments perpendicular to the mid/reference-plane remain straight in deformation (Reissner-Mindlin) and perpendicular to the mid-plane (Kirchhoff). Mathematically $\vec{u}_Q = \vec{u}_P + \vec{\theta}_P \times \vec{\rho}_{PQ}$. Normal stress σ_{zz} is negligible.

EXAMPLE A simply supported circular body of radius R and thickness t is loaded by a point force P acting at the midpoint as shown in the figure. Determine the transverse displacement w at the midpoint by using the plate model. Young's modulus E and Poisson's ratio ν of the isotropic material are constants. Assume that displacement depends on the radial coordinate only.

Answer:
$$w(0) = -\frac{1}{16\pi} \frac{PR^2}{D} \frac{3+\nu}{1+\nu} = -\frac{3}{4\pi} \frac{PR^2}{Et^3} (3+\nu)(1-\nu)$$

BEAM MODEL

Timoshenko

Bernoulli

The primary unknowns are $u(x)$, $v(x)$, $w(x)$, $\phi(x)$, $\theta(x)$, $\psi(x)$. Normal planes to the (material) axis of beam remain planes (Timoshenko) and normal to the axis (Bernoulli) in deformation. Mathematically $\vec{u}_Q = \vec{u}_P + \vec{\theta}_P \times \vec{\rho}_{PQ}$. Transverse normal stress is negligible, i.e., $\sigma_{yy} = \sigma_{zz} \ll \sigma_{xx}$.

BEAM BENDING

Loading case	Deflection (tip)	Rotation (tip)
	$w = \frac{FL^3}{3EI}$	$\theta = -\frac{dw}{dx} = -\frac{FL^2}{2EI}$
	$w = \frac{F(a-L)^2(a+2L)}{6EI}$	$\theta = -\frac{dw}{dx} = -\frac{F(L-a)^2}{2EI}$
	$w = \frac{fL^4}{8EI}$	$\theta = -\frac{dw}{dx} = -\frac{fL^3}{6EI}$
	$w = -\frac{L^2M}{2EI}$	$\theta = -\frac{dw}{dx} = \frac{LM}{EI}$

EXAMPLE A rigidly supported springboard of length L and cross-sectional area $A = bh$ is levelled without loading. Under which conditions displacement at the free end and stress at the support do not exceed the limit values δ and σ_{cr} , respectively, if a person of weight W is standing at the free end? Use the beam model and assume that the stress and the transverse displacement are related by $\sigma_{xx} = -Ez d^2 w / dx^2$.

Answer $4 \frac{WL^3}{Eb h^3} \leq \delta$ and $6 \frac{WL}{bh^2} \leq \sigma_{cr}$

- The relationship between the axial stress and transverse displacement follows from Hooke's law and assumptions of the beam model. Moment equilibrium gives

$$-\int_{-h/2}^{h/2} z \sigma_{xx} b dz - W(L - x) = 0 \Rightarrow$$

$$E \frac{bh^3}{12} \frac{d^2 w}{dx^2} - W(L - x) = 0$$

- Transverse displacement and its derivative vanish at the support. Hence

$$\frac{d^2 w}{dx^2} = 12 \frac{W}{Ebh^3} (L - x) \Rightarrow w(x) = 2 \frac{W}{Ebh^3} x^2 (3L - x).$$

- Therefore $w(L) = 4 \frac{WL^3}{Ebh^3} \leq \delta$ and $\sigma_{\max}(0) = 6 \frac{WL}{bh^2} \leq \sigma_{cr}$. ←

RIGID BODY

The primary unknowns are u , v , w , ϕ , θ , ψ of the translation point. Body may translate and rotate but distance between any two points P and Q is constant. Mathematically, e.g., $\vec{u}_Q = \vec{u}_P + \vec{\theta}_P \times \vec{\rho}_{PQ}$. Forces acting on the body can be represented by a force-moment pair.

1.3 DISPLACEMENT ANALYSIS

- Idealize a complex structure as a set of structural parts, whose behavior can be approximated by using the engineering models (bar, beam, plate, rigid body etc.).
- Write the equilibrium equations for the connection points (Newton **III**), the force-displacement relationships of the structural parts, and constraints concerning the nodal displacements (displacements and rotations should match at the connection points).
- Solve the nodal displacements and rotations and the forces and moments acting on the structural parts (elements in FEM) from the equation system.
- Determine the stress in the structural parts one-by-one according to the engineering model used (optional step).

NEWTON's LAWS OF MOTION

- I** In an inertial frame of reference, an object either remains at rest or continues to move at a constant velocity, unless acted upon by a force.
- II** The vector sum of the forces on an object is equal to the mass of that object multiplied by the acceleration of the object (assuming that the mass is constant).
- III** When one body exerts a force on a second body, the second body simultaneously exerts a force equal in magnitude and opposite in direction on the first body.

Newton's laws in their original forms apply to particles only. The formulation for rigid bodies and deformable bodies requires slight modifications.

QUANTITIES OF ANALYSIS

The primary aim is to find displacements, rotations, forces and moments at the connection points of the structural parts. The components of the vector quantities (magnitude and direction) are taken to be positive in the directions of the coordinate axes.

Vector quantities are invariants in the sense $\vec{a} = a_x \vec{i} + a_y \vec{j} + a_z \vec{k} = a_X \vec{I} + a_Y \vec{J} + a_Z \vec{K}$, and can be transformed from one coordinate system to another using the property.

EXAMPLE A connector bar is welded at its ends to rigid walls. If the right end wall displacement is a , determine the displacements of connection points 1, 2, and 3 and the forces acting on structural parts. Cross sectional area A and Young's modulus of the material E are constants, and the displacement force relationship of a bar is the same as that of a spring with coefficient $k = EA / L$. Model the structure as a collection of two bars (1 and 2).

Answer $u_1 = 0$, $u_2 = u_3 = \frac{1}{2}a$, $u_4 = a$, $F_1 = F_3 = -\frac{1}{2}ka$, $F_2 = F_4 = \frac{1}{2}ka$.

- As the structural parts can be considered as springs of coefficient $k = EA / L$,
 $F_1 = k(u_1 - u_2)$, $F_2 = k(u_2 - u_1)$, $F_3 = EA(u_3 - u_4) / L$, $F_4 = EA(u_4 - u_3) / L$

- The displacement constraints due to the left edge welding, displacement of the right end wall, and integrity of structure at the connection of the structural parts are $u_1 = 0$, $u_4 = a$, and $u_2 = u_3$.
- The force constraints are due to Newton **III** which requires that F_2 and F_3 are equal in magnitude and opposite in signs or $F_2 + F_3 = 0$.

- Altogether, the 8 equations determining the 4 displacement components u_1, u_2, u_3, u_4 and the 4 force components F_1, F_2, F_3, F_4 are given by

$$F_1 = k(u_1 - u_2), \quad F_2 = k(u_2 - u_1), \quad F_3 = k(u_3 - u_4), \quad F_4 = k(u_4 - u_3),$$

$$u_1 = 0, \quad u_4 = a, \quad u_2 = u_3, \quad F_2 + F_3 = 0.$$

- The linear equation system can be solved, e.g., by considering the equations in a proper order (to be discussed later in more detail), by Gauss elimination, by Mathematica, ...

$$u_1 = 0, \quad u_2 = \frac{1}{2}a, \quad u_3 = \frac{1}{2}a, \quad u_4 = a, \quad \leftarrow$$

$$F_1 = -\frac{1}{2}ka, \quad F_2 = \frac{1}{2}ka, \quad F_3 = -\frac{1}{2}ka, \quad F_4 = \frac{1}{2}ka. \quad \leftarrow$$

STRUCTURE

“Structure is a collection of *elements* (earlier structural parts) connected by *nodes* (earlier connection points). Displacement of the structure is defined by nodal translations and rotations of which some are known and some unknown.”

$prb = \{ele, fun\}$ where

$ele = \{prt_1, prt_2, \dots\}$ elements

$fun = \{val_1, val_2, \dots\}$ nodes

Elements

$prt = \{typ, pro, geo\}$ where

$typ = \text{BAR} \mid \text{TORSION} \mid \text{BEAM} \mid \text{RIGID} \mid \dots$ model

$pro = \{p_1, p_2, \dots, p_n\}$ properties

$geo = \text{Point}[\{n_1\}] \mid \text{Line}[\{n_1, n_2\}] \mid \text{Triangle}[\{n_1, n_2, n_3\}] \mid \dots \mid \dots \dots \dots \text{geometry}$

Nodes

$val = \{crd, tra, rot\}$ where

$crd = \{X, Y, Z\} \dots \dots \dots \text{structural coordinates}$

$tra = \{u_X, u_Y, u_Z\} \dots \dots \dots \text{translation components}$

$rot = \{\theta_X, \theta_Y, \theta_Z\} \dots \dots \dots \text{rotation components}$

ELEMENTS

Elements represent the structural parts modelled as solids, plates, beams, or rigid bodies or their simplified versions, external point and boundary forces and moments.

Constraint

$\{\text{SOLID}, \{\{E, \nu\}, \{f_X, f_Y, f_Z, m_X, m_Y, m_Z, \}\}, \text{Tetrahedron}[\{n_1, n_2, n_3, n_4\}]\}$ solid

OPERATIONS

Operations act on structure as defined by *prb*. The main operations of MEC-E1050 are solving the unknowns in displacement analysis and displaying the problem definition in a formatted form.

prb = REFINE[*prb*]refine structure representation
Out = FORMATTED[*prb*] display problem definition
Out = STANDARDFORM[*prb*] display virtual work expression
sol = SOLVE[*prb*]solve the unknowns

EXAMPLE 1.1 A connector bar is welded at its ends to rigid walls. If the right end wall displacement is a , determine the displacements of connection points 1, 2, and 3 and the forces acting on structural parts. Cross sectional area A and Young's modulus of the material E are constants and the displacement force relationship of a bar is the same as that of a spring with coefficient $k = EA / L$. Model the structure as a collection of two bars (1 and 2).

Answer $u_1 = 0$, $u_2 = u_3 = \frac{1}{2}a$, $u_4 = a$, $F_1 = F_3 = -\frac{1}{2}ka$, $F_2 = F_4 = \frac{1}{2}ka$.

- Problem description by $prb = \{ele, fun\}$ and two operations acting on it

```
ele = {  
  {RIGID, {{0, 0, 0}, {0, 0, 0}}, Point[{1]}]},  
  {BAR, {{E}, {A}}, Line[{1, 2}]},  
  {RIGID, {}, Line[{2, 3}]},  
  {BAR, {{E}, {A}}, Line[{3, 4}]},  
  {RIGID, {{a, 0, 0}, {0, 0, 0}}, Point[{4]}]};
```

```
fun = {  
  {{0, 0, 0}, {uX[1], 0, 0}, {0, 0, 0}},  
  {{L, 0, 0}, {uX[2], 0, 0}, {0, 0, 0}},  
  {{L, 0, 0}, {uX[3], 0, 0}, {0, 0, 0}},  
  {{2 L, 0, 0}, {uX[4], 0, 0}, {0, 0, 0}}};
```

```
FORMATTED[{ele, fun}]
```

```
SOLVE[{ele, fun}]
```

- Outcome of the operations is the structure description in table format and solution to the unknowns of the displacement problem (in format of a rule)

EXAMPLE 1.2. A connector bar is welded at its ends to rigid walls. If the right end wall displacement is a , determine the displacement of point 2. Cross sectional area A and Young's modulus of the material E are constants. Model the structure as a collection of two bars (1 and 2).

Answer $u_2 = \frac{1}{2}a$ (Mathematica notebook)

PREREQUISITE: MATRIX ALGEBRA I

Addition	$\mathbf{C} = \mathbf{A} + \mathbf{B}$	$C_{ij} = A_{ij} + B_{ij}$
Multiplication (scalar)	$\mathbf{C} = \alpha \mathbf{A}$	$C_{ij} = \alpha A_{ij}$
Multiplication (matrix)	$\mathbf{C} = \mathbf{A}\mathbf{B}$	$C_{ij} = \sum_{k \in \{1 \dots n\}} A_{ik} B_{kj}$
<hr/>		
Unit matrix	\mathbf{I}	$\delta_{ij} = 1 \quad i = j, \quad \delta_{ij} = 0 \quad i \neq j$
Symmetric matrix	$\mathbf{A} = \mathbf{A}^T$	$A_{ij} = A_{ji}$
Skew symmetric matrix	$\mathbf{A} = -\mathbf{A}^T$	$A_{ij} = -A_{ji}$
Positive definite matrix	$\mathbf{x}^T \mathbf{A} \mathbf{x} > 0 \quad \forall \mathbf{x} \neq 0$	

PREREQUISITE: MATRIX ALGEBRA II

Transpose	\mathbf{A}^T	$A_{ij}^T = A_{ji}$
Inverse	$\mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$	$\sum_{k \in \{1 \dots n\}} A_{ik} A_{kj}^{-1} = \delta_{ij}$
Derivative	$\dot{\mathbf{x}}$	$\dot{x}_i = dx_i / dt$
<hr/>		
Linear equation system	Find \mathbf{x} such that $\mathbf{A}\mathbf{x} = \mathbf{b}$	
Eigenvalue problem	Find all (λ, \mathbf{x}) such that $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = 0$	
Eigenvalue composition	$\mathbf{A} = \mathbf{X}\boldsymbol{\lambda}\mathbf{X}^{-1}$, where $\mathbf{X} = [\mathbf{x}_1 \dots \mathbf{x}_n]$ and $\boldsymbol{\lambda} = \text{diag}[\lambda_1 \dots \lambda_n]$	
Matrix function	If $\mathbf{A} = \mathbf{X}\boldsymbol{\lambda}\mathbf{X}^{-1}$, then $f(\mathbf{A}) = \mathbf{X}f(\boldsymbol{\lambda})\mathbf{X}^{-1}$	

EXAMPLE. Determine the square \mathbf{A}^2 and inverse \mathbf{A}^{-1} of \mathbf{A} if

$$\mathbf{A} = \begin{bmatrix} 5 & 2 \\ -1 & 3 \end{bmatrix} \text{ (note: } \mathbf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \Rightarrow \mathbf{A}^{-1} = \frac{1}{ad-bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} \text{)}$$

Matrix squared $\mathbf{A}^2 = \begin{bmatrix} 5 & 2 \\ -1 & 3 \end{bmatrix} \begin{bmatrix} 5 & 2 \\ -1 & 3 \end{bmatrix} = \begin{bmatrix} 23 & 16 \\ -8 & 7 \end{bmatrix} \quad \blackleftarrow$

Inverse matrix $\mathbf{A}^{-1} = \begin{bmatrix} 5 & 2 \\ -1 & 3 \end{bmatrix}^{-1} = \frac{1}{17} \begin{bmatrix} 3 & -2 \\ 1 & 5 \end{bmatrix} \quad \blackleftarrow$

From the viewpoint of computational complexity, solving a system of linear equations $\mathbf{Ax} = \mathbf{b}$ by Gauss elimination makes more sense than using the matrix inverse with $\mathbf{x} = \mathbf{A}^{-1}\mathbf{b}$!

PREREQUISITE: MATRIX ALGEBRA III

Partitioned matrix

$$\mathbf{A} = \begin{bmatrix} \mathbf{a}_{11} & \mathbf{a}_{12} \\ \mathbf{a}_{21} & \mathbf{a}_{22} \end{bmatrix} \quad \& \quad \mathbf{B} = \begin{Bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{Bmatrix}$$

Transpose

$$\mathbf{A}^T = \begin{bmatrix} \mathbf{a}_{11}^T & \mathbf{a}_{21}^T \\ \mathbf{a}_{12}^T & \mathbf{a}_{22}^T \end{bmatrix}$$

block or sub-matrix

Multiplication

$$\mathbf{AB} = \begin{bmatrix} \mathbf{a}_{11} & \mathbf{a}_{12} \\ \mathbf{a}_{21} & \mathbf{a}_{22} \end{bmatrix} \begin{Bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \end{Bmatrix} = \begin{Bmatrix} \mathbf{a}_{11}\mathbf{b}_1 + \mathbf{a}_{12}\mathbf{b}_2 \\ \mathbf{a}_{21}\mathbf{b}_1 + \mathbf{a}_{22}\mathbf{b}_2 \end{Bmatrix}$$

The rules are the same as with the ordinary matrices. The sizes of the blocks need to be consistent in operations like transposing and multiplication!

EXAMPLE Determine the displacements w_i , if $i \in \{1, 2, 3\}$ the vector of displacements \mathbf{a} , stiffness matrix \mathbf{K} , and the loading vector \mathbf{F} of the equilibrium equations $\mathbf{Ka} - \mathbf{F} = 0$ are given by

$$\mathbf{a} = \begin{Bmatrix} w_1 \\ w_2 \\ w_3 \end{Bmatrix}, \quad \mathbf{K} = k \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{bmatrix}, \quad \text{and} \quad \mathbf{F} = P \begin{Bmatrix} 0 \\ 0 \\ 1 \end{Bmatrix}.$$

Answer $w_1 = \frac{P}{k}$, $w_2 = 2\frac{P}{k}$, and $w_3 = 3\frac{P}{k}$.

- With linear equation systems of more than two unknowns, using a matrix inverse is not efficient. Gauss elimination is based on row operations aiming at an upper diagonal matrix. After that, solution for the unknowns is obtained step-by-step starting from the last equation. In the present problem

$$k \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{bmatrix} \begin{Bmatrix} w_1 \\ w_2 \\ w_3 \end{Bmatrix} = P \begin{Bmatrix} 0 \\ 0 \\ 1 \end{Bmatrix}.$$

- Let us multiply the 2:nd equation by 2 and add to it equation 1 to get

$$k \begin{bmatrix} 2 & -1 & 0 \\ -2 & 4 & -2 \\ 0 & -1 & 1 \end{bmatrix} \begin{Bmatrix} w_1 \\ w_2 \\ w_3 \end{Bmatrix} = P \begin{Bmatrix} 0 \\ 0 \\ 1 \end{Bmatrix} \Rightarrow k \begin{bmatrix} 2 & -1 & 0 \\ 0 & 3 & -2 \\ 0 & -1 & 1 \end{bmatrix} \begin{Bmatrix} w_1 \\ w_2 \\ w_3 \end{Bmatrix} = P \begin{Bmatrix} 0 \\ 0 \\ 1 \end{Bmatrix}.$$

- Let us multiply 3:rd equation by 3 and add to it the 2:nd equation to get the upper triangular matrix.

$$k \begin{bmatrix} 2 & -1 & 0 \\ 0 & 3 & -2 \\ 0 & -3 & 3 \end{bmatrix} \begin{Bmatrix} w_1 \\ w_2 \\ w_3 \end{Bmatrix} = P \begin{Bmatrix} 0 \\ 0 \\ 3 \end{Bmatrix} \Rightarrow k \begin{bmatrix} 2 & -1 & 0 \\ 0 & 3 & -2 \\ 0 & 0 & 1 \end{bmatrix} \begin{Bmatrix} w_1 \\ w_2 \\ w_3 \end{Bmatrix} = P \begin{Bmatrix} 0 \\ 0 \\ 3 \end{Bmatrix}.$$

- After these steps, solution is obtained step-by-step starting from the last equation:

$$kw_3 = 3P \Leftrightarrow w_3 = 3\frac{P}{k}, \quad \leftarrow$$

$$k(3w_2 - 2w_3) = 0 \Rightarrow w_2 = \frac{2}{3}w_3 = 2\frac{P}{k}, \quad \leftarrow$$

$$k(2w_1 - w_2) = 0 \Rightarrow w_1 = \frac{1}{2}w_2 = \frac{P}{k}. \quad \leftarrow$$
